Evapotranspiration from Natural Vegetation in the Central Valley of California

CWEMF 2014 Annual Meeting

Folsom, CA February 25, 2014

Daniel Howes, Ph.D., P.E.

Assistant Professor and Senior Engineer djhowes@calpoly.edu

moving water in new directions **Irrigation Training and Research Center (ITRC)** California Polytechnic State University San Luis Obispo, California <u>www.itrc.org</u> (805) 756-2434 Phyllis Fox, Ph.D.

Environmental Consultant

Paul Hutton, Ph.D., P.E.

Senior Engineer Metropolitan Water District

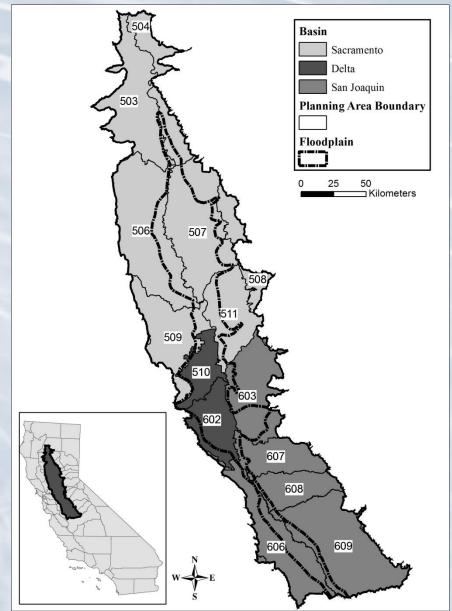

Introduction

- Evapotranspiration estimates for natural vegetation are important for:
 - Restoration activities
 - Hydrologic evaluations/modeling
 - Historical water consumption
 - Potential future water consumption
- Concurrent evaluation of pre-developed natural flow out of the Delta
 - Requires ET estimates of vegetation in predeveloped CA (area that flows to the Delta)

Central Valley Floor

Planning Areas (CDWR, 2005)

ITRC 2014

Introduction

 Direct measurement of plant evapotranspiration is challenging and there is a need to estimate ET in different time periods and locations

 Measurements in one location are not directly transferable to another (climate, management, soils, etc.)

Issues

- Agriculture has standardized on the use of reference evapotranspiration/crop coefficient methodology to achieve transferability
 - (standard equations for reference crop evapotranspiration: ASCE 2005 Modified Penman-Monteith)
- Same standardization is not found for estimating ET of natural or native vegetation
- Researchers base the reference on:
 - Evaporation pans
 - Priestley-Taylor
 - Blaney-Criddle
 - Jensen-Haise
 - One of the Penman-Monteith versions

Issues Continued

- Quality of the reference data, lack of standardization, and issues with transferability limits the direct use of research measurements by other users
- Quality E pan data for example can be very limited
- With the increase in weather station networks and standards for site maintenance, following the agriculture standards seems like a logical step forward for natural vegetation
 - Spatial ETo estimates (e.g. SpatialCIMIS)
- This will promote further work and use of existing research for modeling and computation of natural vegetation ET

ETc for Ag Crops

- Standard Reference Crops
 - Alfalfa or tall crop (ETr)
 - Grass or short crop (ETo) (California)
- Special reference evapotranspiration weather station networks are proliferating
 - CIMIS
 - Agrimet
 - CoAgMet and others

Objectives of This Study

- Estimate the evapotranspiration from natural vegetation in California's Central Valley using:
 - Estimated grass reference based vegetation coefficients (Kv's) for non-water stressed vegetation based on past research
 - For vegetation relying on rainfall, a daily soil water balance with the dual crop coefficient method
 - Daily and monthly ETo and precip for each planning area from 1922-2009 (CDWR – Orang et al. 2013)

Methodology – Kv approach

- Reviewed over 120 references on evapotranspiration from a variety of natural vegetation types
- Limited results to data:
 - presented monthly or more frequently
 - measured within surrounding vegetation using a standard/verified approach
 - most were from 1950 to present
 - focused on studies in the western U.S. (arid/semi-arid environments)

Methodology - Kv (cont.)

- Computed vegetation coefficients on a monthly basis $Kv = \frac{ETc}{ETo}$
- ETo = grass reference evapotranspiration
- In some cases, ETo weather stations were not available in the area where the study was conducted
- Used a calibrated Hargreaves Equation to compute ETo for those cases

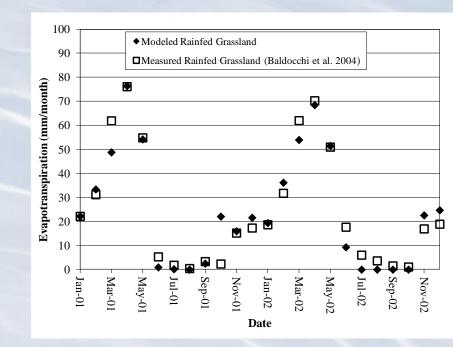

Methodology – Soil Water Balance

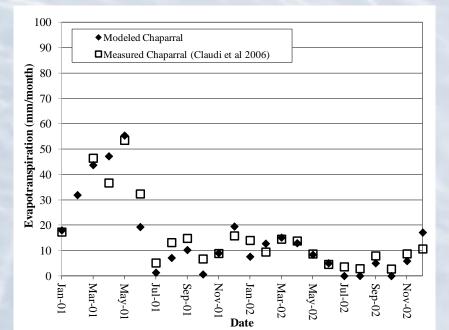

- Vegetation relying on rainfall
- ETv depends on rainfall and is low in summer
- Soil water balance using the FAO 56 dual crop coefficient approach
- Model calibrated based on measured data from other studies
 - Rainfed grasses and foothill oak savannas (Baldocchi et al. 2004)
 - Chaparral (Claudio et al. 2006)

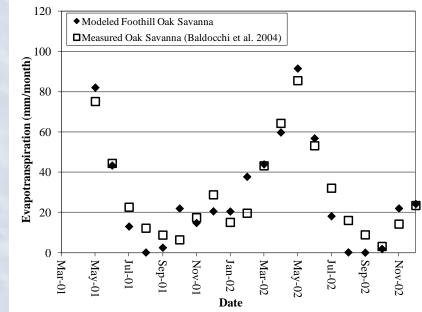

SWB Calibration

- Adjusting
 - Basal Kv (canopy)
 - Development periodSMD at onset of stress

Results – Kv values

- Comprehensive tables in future paper
 - Large stand wetlands (5 studies)
 - Seasonal wetlands (2 studies)
 - Small stand wetlands (5 studies)
 - Large stand riparian forest (4 studies)
 - Smaller stand riparian forest (1 study)
 - Perennial grasses (5 studies)
 - Saltbush (4 studies)
 - Shallow open water (3 studies)

moving water in new directions

Conclusions

- For non-water stressed vegetation, Kv values showed good agreement between independent studies
- A list of grass reference based Kv values have been generated from past research for use in estimating vegetation in arid/semi arid climates
- For vegetation relying on rainfall, a soil water balance model was used to estimate ET
 - Calibration of the model based on measured values
